

Notes

Data checks, sources, definitions and limitations for the Dashboard.

Data checks

Check	Count
Negative ages	1
Negative wait days	5
Rows excluded	6

6 of the appointments were excluded from the analysis: 1 had a negative age and 5 had an appointment date before the booking date. These rows were flagged (Valid = 0), not deleted.

Date range

Measure	Date
Earliest appointment	29/04/2016
Latest appointment	08/06/2016

Data observations

- Only two days of data (24-25 May) for the week of 23 May; cause not stated in the dataset.
- Average wait increases with age (9.6 to 11.3 days) while no-show rate decreases, so wait time does not account for the age difference.
- No-show rates rise from 13.5% for appointments booked within 7 days to 31.7% for 8-30 days and 33.0% for 31+ days. Most of the increase occurs after the first week, suggesting priority should go to offering more early slots and to targeted reminders for later bookings.

About this workbook

Purpose	Excel KPI dashboard analysing appointment no-shows using a public dataset. Not data from a New Zealand practice.
Data source	Medical Appointment No Shows (Kaggle, https://www.kaggle.com/datasets/joniarroba/noshowappointments). Brazilian clinic appointments, 29 Apr to 8 Jun 2016.
KPI definitions	No-show rate = no-shows ÷ valid appointments. Wait days = appointment date minus booking date. Valid = 1 unless age is negative or the appointment date is before the booking date.
Assumptions and limitations	Target no-show rate of 15% is an assumption, not from the dataset. Weeks starting 25 Apr, 23 May and 6 Jun are incomplete (only two days of data for 23 May; cause not stated in the dataset). Findings show associations, not causes. For example, we don't know how the clinic chose which patients received an SMS.
How to update	Paste new rows below the Data table. Helper columns and Calc formulas update automatically; add any new week to the weekly table on Calc.
